CS648 Assignment 2

SWASTIK SHARMA (14741) ANUBHAV SHRIVASTAVA (14114)

1. 2-Dimensional Pattern Matching

1.
Notations : Let T be the text bit-string and P the pattern bit-string. Size of T is n and P is m.
$M(P)$ is mapping of the pattern P to a $2X2$ matrix as given in the problem statement.
$M(P)^{-1}$ is the inverse matrix to M(P). Let l and r be two indices in T s.t. $1 \leq l \leq r \leq n$.
$T[l, r]$ is the substring starting at index l and ending at r.
Consequently, $M(T[l, r])$ is mapping of $T[l, r]$ to $2X2$ matrix as given in the problem statement.

$$M(\epsilon) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \qquad M(0) = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \qquad M(1) = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \qquad M(0)^{-1} = \begin{bmatrix} 1 & 0 \\ -1 & 1 \end{bmatrix} \qquad M(1)^{-1} = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix}$$

Algorithm : Basically, we will compare $M(P)$ with $M(T[i, i+m-1])$ $\forall$ i in $[1, n-m+1]$.
We will calculate $M(P)$ by right multiplying corresponding $M(P[i])$ for i from 1 to m to an identity matrix. Similiarly,we will calcuate $M(T[1, m])$ After that to get, $M(T[i, i+m-1])$ for i > 1, we will take $M(T[i-1, i+m-2])$, right multiply $M(T[i+m, i+m])$ and left multiply $M(T[i-1, i-1])^{-1}$ to it.
The following pseudo code formalize the above algorithm.

$pattern \leftarrow M(P);$
$current \leftarrow M(T[1, m]);$
$for\ i = 1\ to\ n - m + 1$
    $if\ pattern == current$
        print "Pattern present at index i";
    $if\ i < n - m + 1$
        current = $multiply(current, M(T[i+m, i+m]));$
        current = $multiply(M(T[i, i]), current);$

Order Analysis :
Calculating $M(P)$ takes $O(m)$ time
Calculating $M(T[1, m])$ takes $O(m)$ time
Loop Runs $n - m + 1$ times and at each iteration we do a $O(1)$ computation.Hence loop takes O(n - m + 1) time.
Overall Complexity = $O(n + m)$ time.

2.
Notation :
Let M be a matrix then M mod p denotes a matrix in which all entries of M are replaced by their modulo with p.
Hence, We perform the above algorithm but at each step, while multiplying two matrices, we take modulo with p.
Let $M(A)$ and $M(B)$ be two matrices which are mapping of string A and B of size m.
$\pi(t)$ = number of primes less than equal to t.

Now, if $M(A) == M(B)$ then $M(A)\ mod\ p == M(A)\ mod\ p$ then $A == B$ which is true.
But if $A\ != B$ and then $M(A)\ != M(B)$ then it might be possible that $M(A)\ mod\ p == M(B)\ mod\ p$. which will imply that $A == B$ which is not true.
Hence, this algorithm will fail iff $M(A)\ != M(B)$ and $M(A)\ mod\ p == M(B)\ mod\ p$.
Let $D = M(A) - M(B)$
$M(A)\ mod\ p == M(B)\ mod\ p$
$\implies M(A) - M(B)\ mod\ p == 0$ (where 0 is $2X2$ null matrix)
$\implies D\ mod\ p == 0$

Hence, every entry of D is muliple of p, or conversely p is factor of every entry of D.
Now, take any entry of D *(say x)*. Now, x is bounded by m^{th} Fibonacci number which is bounded by 2^m;
Now, any number N has at most $logN$ factors hence x has atmost m factors or atmost n factors (m $\leq$ n).
Let say we choose p uniformly randomly from range $[2, t]$ then probability that a factor of x was choosen was $\frac{n}{\pi(t)}$
There are four elements of D and event that p is a factor of one of the element is independent of the event that p is a factor of other element of D.
Hence probability that p was a factor of all of the element $\leq (\frac{n}{\pi(t)})^4$.
We want this probability to be less than $\frac{1}{n^4}$.
Hence, we want $\frac{n}{\pi(t)}$ to be less that $\frac{1}{n}$.

Putting $t = n^2 logn$ and $\pi(t) = \frac{t}{logt}$. *(As done in class)*
We get this probability to be less $\frac{1}{n^4}$.

3.
Notation :
Here we assume that all operation are accompanied by a modulo operation by p which is chosen in the begining.
Let S be 2-D bit-matrix and $S(i,j)$ denotes the element of i^{th} row and j^{th} column.
$PrefixProduct(i,j)$ = Product of all the $M(S(k,j))$ s.t. $1 \leq$ k $\leq$ i.
i.e. $PrefixProduct(i,j) = M(S(1,j)) * M(S(2,j)) * ... * M(S(i,j))$
$PrefixProductInverse(i,j)$ = Matrix inverse of $PrefixProduct(i,j)$
i.e. $PrefixProductInverse(i,j) = M(S(i,j))^{-1} * M(S(i-1,j))^{-1} * ... * M(S(1,j))^{-1}$

Now let us assume there is a matrix X of size NXM then we have map this matrix to 2X2 matrix M(X)
We define this map as follows:
If X is column matrix, cut this matrix into two submatrix by cutting at any row. Let U be upper column matrix and L be the lower one.
Then $M(X) = M(U) * M(L)$
If X is not a column matrix,cut this at any column, let L be the submatrix left of this line and R be the one right to it. Then $M(X) = M(L) * M(R)$
Now we have defined the new mapping M, we can state our algorithm.

Algorithm : Let T be the text nXn 2-D bit-matrix and P be the pattern mXm 2-D bit-matrix. $T(i,j)$ is the element at the i^{th} row and j^{th} column.
First we show how to calculate $PrefixProduct(i,j)$ and $PrefixProductInverse$ for matrix T in $O(n^2)$ time.
$PrefixProduct(1,j)$ and $PrefixProductInverse(1,j)$ will be simply the $M$and M^{-1} of the corresponding element. To calculate them for other rows just use the $PrefixProduct$ and $PrefixProductInverse$ of previous row.
Following pseudocode describes our algorithm :

for j = 1 to n
    $PrefixProduct(1,j) = M(T(1,j))$
    $PrefixProductInverse(1,j) = M(T(1,j))^{-1}$
for i = 2 to n
    for j = 1 to n
        $PrefixProduct(i,j) = PrefixProduct(i-1,j) * M(T(i,j))$
        $PrefixProductInverse(i,j) = M(T(i,j))^{-1} * PrefixProductInverse(i-1,j)$

Also we calculate $M(P)$ in $O(m^2)$ time.

Initialize M(P) = I_{2X2}
for i = 1 to m
    for j = 1 to m
        $M(P) = M(P) * M(T(j,i))$

Now we have to calculate mapping of every submatrix of size m of matrix T. Let $M(T(i,j))$ is the mapping of submatrix of size m ending at (i,j) in T. $m \leq i, j \leq n$. We will calculate this mapping in $O(n^2)$ time as follows :
First we calculate $M_c(i,j)$ which is product of all the $M(T[k,j])$ such that $i-m+1 \leq k \leq i$, $m \leq i \leq n$,$1 \leq j \leq n$
Also we will calculate $M_c(i,j)^{-1}$ with it. We can calculate these both in $O(n^2)$ as follows:

for i = m to n
    for j = 1 to n
        If $i = m$
            $M_c(m,j) = PrefixProduct(m,j)$
            $M_c(m,j)^{-1} = PrefixProductInverse(m,j)$
        else
            $M_c(i,j) = PrefixProductInverse(i-m,j) * PrefixProduct(i,j)$
            $M_c(i,j)^{-1} = PrefixProductInverse(i,j) * PrefixProduct(i-m,j)$

Now with help of this we can calculate $M(T(i,j))$ in $O(n^2)$ as follows :

for i = m to n
    for j = m to n
        if $j = m$
            Initialize $M(T(i,j)) = I_{2X2}$
            for k = 1 to m
                $M(T(i,j)) = M(T(i,j)) * M_c(i,k)$
        else
            $M(T(i,j)) = M_c(i,j-m)^{-1} * M(T(i,j-1)) * M_c(i,j)$

For $n-m+1$ elements we take $O(m)$ time and for rest of the elements we take $O(1)$ time. Hence total time = $O(m*(n-m+1))$ + $O((n-m+1)*(n-m+1)) = O(n^2)$
Hence we just go at each i,j s.t m $\leq$ i,j $\leq$ n,compare M(P) with $M(T(i,j))$ in $O(1)$ time which take overall $O(n^2)$
Now,for the error probability, we again recieve two $2X2$ matrix and compare them in our algorithm. Hence,we can again choose prime as done in last part and get the same error probability i.e. $\frac{1}{n^4}$.

2. How well did you internalize the proof of Chernoff bound ?

1. Probability that number of coin tosses required to get n heads is greater than $2n(1+\delta)$ is same as Probability of getting less than or equal $n-1$ heads out $2n(1+\delta)-1$ coin tosses.
For given geometrically distributed random variable, we know that expected value is $\frac{1}{p}$ which is given 2 , hence $p = \frac{1}{2}$.

$$X_i^{‘} = \begin{cases} 1 & \text{if head is obtained at } i_{th} \text{ iteration} \\ 0 & \text{otherwise} \end{cases}$$

$E[X_i^{‘}] = \frac{1}{2} * 1 + \frac{1}{2} * 0 = \frac{1}{2}$.

$X^{‘} = \sum_{i=1}^{2n(1+\delta)-1} X_i^{‘}$

$E[X^{‘}] = n(1+\delta) - \frac{1}{2}$

Assuming $n \gg \frac{1}{2}$, we get $E[X^{‘}] = n(1+\delta)$

P($X^{‘} \leq (n-1)$)

= P($X^{‘} \leq (n-1)\frac{E[X^{‘}]}{(1+\delta)n}$)

= P($X^{‘} \leq (1 - \frac{n\delta+1}{n(1+\delta)}) * E[X^{‘}]$)

$\leq$ P($X^{‘} \leq (1 - \frac{\delta}{\delta+1}) * E[X^{‘}]$) (As $\frac{n\delta+1}{n(1+\delta)} > \frac{\delta}{\delta+1}$)

= P($X^{‘} \leq (1-\delta^{‘}) * E[X^{‘}]$) By letting $\delta^{‘} = \frac{\delta}{\delta+1}$

$\leq (\frac{e^{-\delta^{‘}}}{(1-\delta^{‘})^{1-\delta^{‘}}})^{E[X^{‘}]}$

Putting value of $\delta^{‘}$, we get

$\leq ((1+\delta)e^{-\delta})^n$

2. According to Markov's Inequality

P(X $\geq$ a) $\leq \frac{E[X]}{a}$ if X(ω) $\geq 0 \;\forall\; \omega \in \Omega$

$\because$ X(ω) $\in \mathbb{N}$

P(X $\geq (1+\delta)\mu$)

= P($e^{tx} \geq e^{(1+\delta)t\mu}$) $\leq \frac{E[e^{tx}]}{e^{(1+\delta)t\mu}}$

E[e^{tX}]

$= \mathrm{E}[e^{tX_1+tX_2+tX_3 \ldots +tX_n}]$

$= \prod_{i=1}^{n} E[e^{tX_i}]$

$\mathrm{E}[e^{tX_i}] = \frac{e^t}{2} + \frac{e^{2t}}{4} + \frac{e^{3t}}{8} \ldots\ldots = \frac{e^t}{2(1-\frac{e^t}{2})} = \frac{e^t}{2-e^t}$
$\mathrm{E}[e^{tX}] = \prod_{i=1}^{n} E[e^{tX_i}] = (\frac{e^t}{2-e^t})^n$

Now $\mu = 2n$

$\mathrm{P}(\mathrm{X} \geq 2n(1+\delta)) \leq (\frac{e^t}{(2-e^t)e^{2t(1+\delta)}})^n$

Now differentiating w.r.t t to get the $minima$ we get

$\mathrm{P}(\mathrm{X} \geq 2n(1+\delta)) \leq (\frac{(1+\delta)^{2(1+\delta)}}{(1+2\delta)^{1+2\delta}})^n$

3.
Claim : Bound obtained from 2nd part is better

Proof : Bound obtained in 1st part *(say b1)* $= (\frac{1+\delta}{e^\delta})^n$

Bound obtained in 2nd part *(say b2)* $= (\frac{(1+\delta)^{2(1+\delta)}}{(1+2\delta)^{1+2\delta}})^n$

To prove $\frac{b1}{b2} \geq 1$ $\frac{b1}{b2} = (\frac{(1+\delta)(1+2\delta)^{1+2\delta}}{((1+\delta)^{2(1+\delta)})e^\delta})^n$

Taking ln on both sides,we get

$n(ln(1+\delta) - \delta - 2(1+\delta)ln(1+\delta) + (2\delta+1) * ln(1+2\delta)) \geq 0$

$(2\delta+1)(ln(\frac{1+2\delta}{1+\delta})) > \delta$

$ln(\frac{1+2\delta}{1+\delta}) = ln(1+\frac{\delta}{1+\delta}) > \frac{\delta}{\delta+1}$ - $\frac{\delta^2}{2(\delta+1)^2}$

LHS $> (2\delta+1)(\frac{\delta}{\delta+1} - \frac{\delta^2}{2(\delta+1)^2}) = \frac{\delta(2\delta+1)(\delta+2)}{2(\delta+1)^2} = \frac{\delta(2\delta^2+5\delta+2)}{(2\delta^2+4\delta+2)} > \delta$
Hence proved.

3. Estimating biasness of a coin

Strategy: We toss the coin N times, Let H be the random variable denoting the number of heads in N coin tosses. We report $\widetilde{p}$ to be $\frac{H}{N}$.
Now, given ϵ, δ and a, we will estimate the value of N so that the following probability hold.
$\Pr[|p - \widetilde{p}| > p\epsilon] < \delta$

$\implies \Pr[\widetilde{p} < p(1-\epsilon)] + \Pr[\widetilde{p} > p(1+\epsilon)] < \delta$

$\implies \Pr[N\widetilde{p} < Np(1-\epsilon)] + \Pr[N\widetilde{p} > Np(1+\epsilon)] < \delta$

$\implies \Pr[H < E[H](1-\epsilon)] + \Pr[H > E[H](1+\epsilon)] < \delta$

Now $\Pr[H < E[H](1-\epsilon)] + \Pr[H > E[H](1+\epsilon)]$

$< e^{\frac{-N\epsilon^2 p}{2}} + e^{\frac{-N\epsilon^2 p}{4}}$

$< 2e^{\frac{-N\epsilon^2 p}{4}}$

$< 2e^{\frac{-N\epsilon^2 a}{4}}$

If we have this term to be less than δ then our Probability condition will hold.

$2e^{\frac{-N\epsilon^2 a}{4}} < \delta$

$\implies \frac{-N\epsilon^2 a}{4} < ln(\frac{\delta}{2})$

$N > 4\frac{ln(\frac{2}{\delta})}{a\epsilon^2}$
